RE: Herbert Miller #18087

The above employee was first seen in the Medical Department on 3-24-52 when he complained of a dull pain in the left middle chest area. He said he felt the pain when he was doing his regular work. He was examined, and it was observed that he had a sticking pain, on deep respiration, over the left fifth inter-space in the axillary line. A chest binder was applied and he was given a sedative. He was seen again on June 13, 1952, he brought in a note from his family doctor who said, "I am treating Herbert Miller for tracheo-bronchitis aggrevated by in halation from the type of work he is doing at present. Avoidance of this dust inhalation would be beneficial for him."

X-rays were taken of him on that date and they were found to be negative. He still complained of a cough in his chest, his temp. was 99.4°. He was advised to go home and continue treatment until his symptoms cleared up.

On July 24, 1952, in the Medical Department, his chest was found to be clear and he was approved to return to work.

He was re-examined on August 18, 1952 after he had been to St. Petersburg Florida on a Leave of Absence. He stated that he had no cough, no pain in his chest, no expectoration, and he was feeling good. Examination of his chest showed it to be clear and resonant, no rales were present.
He informed me that for the past year he had been working on a pilot project for Dr. Speel and prior to that he had worked with Mr. Tucker. He said he would be happy to work for Mr. Tucker and he was approved to return to work.

The diagnosis of Herbert Miller is tracheobronchitis of unknown origin. Repeated X-rays taken of Herbert Miller on June 17, 1952 and August 18, 1952 show no evidence of occupational disease.
