From our discussions, we have gained a better understanding of your problem in obtaining accurate feed weights on asbestos ore. There seems to be mutual agreement that the best way to proceed is to use the actual quantity of each product produced in a month divided by the standard recovery for that product to obtain a calculated feed weight. The total for all products will represent the ore usage from the stockpile for the month.

The belt scale weight should be used as a check against this calculation, but we feel that the above method should be the one used to determine the usage of record each month.

We will be interested in knowing the results of your next ore pile exhaustion which we understand may occur sometime next summer.
