ACKNOWLEDGEMENTS

We wish to express our thanks to Mr. Voisinet, Miss Plechaty, Miss Starkey and Mrs. Jennifer Neelen for their assistance and patience during the gathering of the data.

Computerization and statistical analysis were performed under the supervision of Dr. Carol K. Redmond, Professor of the Department of Biostatistics at the University of Pittsburgh Graduate School of Public Health, who also consulted on the planning of the study. Dr. Hannen Liu, on Dr. Redmond's staff constructed a Dictionary of ICDA Codes and Mr. Refik Burgut prepared the Job Title Listing.

INTRODUCTION

This study of Union Carbide Corporation silanes workers was part of a larger, jointly-sponsored, project for the U.S. silicone producing companies. That study was reported to the Committee representing the producers on September 26, 1979 in the form of composite results of the total study. From the beginning, it was recognized that no one company would have a sufficient number of employees from which to draw conclusions which would be applicable to the general industry, and for this reason, the findings reported here for Union Carbide workers should be interpreted as relevant to this company only.

METHODS

The initial visit to the Sistersville, West Virginia Plant was made on February 14, 1977, at which time IHF personnel met with Messrs. O'Connors, Boyde, Blink and Dr. Bailey. The methodology of the study was discussed and the type and availability of both medical and employment records were explored. At this time, it was believed that a computer printout of employees on the payroll in 1955 could be made available, and samples of the various forms used were provided to IHF.

Union Carbide trial exhibit UC-4189: Industrial Health Foundation Report to Union Carbide on an Epidemiology Stud... Published by AsbestosClaims.Law
ACL Doc 18783 · Page 5 of 104 asbestosclaims.law/library/18783/5

This plant originated in 1955 with about 200 employees. At present there are about 600 workers of whom 282 are hourly and, because of a low turnover, it was estimated that the total number of persons ever employed was about 800. We were told that management was aware of only about 20 deaths among the workforce since 1955, of which only one was work-related.

Subsequent visits were made in September, November and December of 1977; and February and October of 1978. During these visits, information obtained from computer printouts was reviewed to determine those employees who would constitute the universe. The information on the computer sheets, however, contained only names of active employees, and was of limited use in establishing a cohort, and considerable effort was expended in an attempt to determine those workers who were on the payroll as of January 1, 1955. When we were later provided with a list of all employees since the opening of the plant, by man-number, it was comparatively easy to select a cohort. The cohort had been defined as all workers employed for at least five years in an exposed occupation, who were on the payroll on January 1, 1955, or hired between that date and December 31, 1968. The cohort was to be followed to the end of 1975.

All available employment records of workers in the cohort were microfilmed in this period.

Union Carbide trial exhibit UC-4189: Industrial Health Foundation Report to Union Carbide on an Epidemiology Stud... Published by AsbestosClaims.Law
ACL Doc 18783 · Page 6 of 104 asbestosclaims.law/library/18783/6

Because there is presently no disease state known to be specifically associated with exposure to organosilicon compounds, it was felt wise to look for patterns of disease which might emerge during the study of the cohort. It was originally thought that such information could be obtained from sickness and accident records, and we understood during the original visit that such were available. Subsequently, however, it was found that this was not the case, and it then became necessary to review each dispensary record in detail. Authorizations were solicited from the employees and, where no signed authorization was obtained, the medical records were reviewed by Union Carbide medical personnel and not by the IHF investigators.

All dispensary visits not of a traumatic nature were hand-recorded chronologically. Special attention was paid to complaints of symptoms which could conceivably arise as result of exposure to chemicals, such as dermatitis, irritation of eyes or mucous membranes, chest tightness, jaundice, and blood dyscrasias.

At Union Carbide, the periodic physical examinations of appropriate groups of workers have for some time included extensive blood chemistry and, more recently, ventilatory function tests. Chest x-rays on all dust-exposed workers have been included. Results of these examinations were recorded and computerized in an attempt to elicit any evidence of the development of work-related disease.

ACL Doc 18783 · Page 7 of 104 asbestosclaims.law/library/18783/7

All collected data were analyzed at IHF headquarters and coded in a form suitable for computerization.

Job titles in this plant were reviewed with Mr. Voisinet because the same job in different companies frequently has a different title. In order to determine the type of exposure inherent in a given job it was necessary to ascertain the type of work and, therefore the exposure, indicated by the job titles at Union Carbide. Environmental testing has been performed over the past couple of years only, and it was intended that atmospheric levels would be reviewed if any excess in mortality or morbidity were to be found in any area.

STATISTICAL METHODS

The Standardized Mortality Ratio (SMR) is computed as the ratio of the number of observed deaths to the number of expected deaths, summation being taken by calendar year and by age group.

The SMR's for this study are race-specific and are adjusted for age by the indirect method, utilizing the total U.S. male white and nonwhite male populations as standard. Age- and cause-specific mortality rates in the standard population for the years 1955, 1960, 1965 and 1970 were applied to age-specific subgroups of person-years at risk, by area or zone, in each of five-year calendar periods from 1953 to 1975 to obtain the number of deaths expected in each subgroup.

Union Carbide trial exhibit UC-4189: Industrial Health Foundation Report to Union Carbide on an Epidemiology Stud... Published by AsbestosClaims.Law
ACL Doc 18783 · Page 8 of 104 asbestosclaims.law/library/18783/8

The 1970 U.S. rates were used as the comparison for the entire interval from 1968 through 1975 and the SMR's then computed. Significant deviations from unity, indicating an excess or a deficit in a particular work area relative to the control group, are identified by examining confidence intervals placed on the SMR parameter. Under the assumption of a Poisson distribution of deaths, these bounds are readily obtained.(1) SMR's are considered to be significantly different at the 5% level if the 95% confidence intervals do not contain a value of 100.

Since the observation period for this study spans a time period covered partly by the 7th Revision ICDA(2) and partly by the 8th Revision ICDA,(3) an adjustment was made when using total rates for the years 1953 through 1975, so that causes of death coded in the two revisions would be as comparable as possible. This adjustment was based on a comparability ratio(4) which was computed by using the results of all deaths occurring in 1966, coded according to the 7th Revision, and a random sample of these same deaths stratified by cause, and coded according to the 8th Revision. The ratios were computed by dividing the numbers of deaths estimated from the stratified random sample (coded by the 8th Revision) by the numbers of deaths assigned to the most comparable causes when coded by the 7th Revision. A more detailed description of these procedures can be found in the literature.(5),(6)

RESULTS

The universe available for study at the Sistersville Plant included some 817 persons, of whom 375 met the requirements for inclusion in the cohort as defined. Unfortunately employment records on 35 workers could not be furnished by the employment department. Even though termination dates were later provided which would indicate that the employment of all 35 was less than five years, it is acknowledged that this was not confirmed by the researchers and thus may be open to criticism. It could be argued that some of these should have been in the cohort, and, if deceased, would change the results.

Of the 375 known to be in the cohort, 325 were found to be alive and active on December 31, 1975. From pension payments it was determined that 12 retirees were also living on that date. Five workers were found to have died while still actively employed. Of the remaining 33, it was subsequently determined through Social Security and Motor Vehicle Registration records that 29 were living on December 31, 1975, having either terminated their employment or having been transferred to another Union Carbide Plant. Two had died following retirement, and two after termination or transfer. Thus, 366, or 97.6% of the cohort were living at the end of the observation period and 9 were dead.

A summary is presented in Table 1. The age distribution of the cohort is shown in Table 2, and deaths by age group and the ages at death are shown in Table 3. Causes of death are given in Table 4.

DISCUSSION

This small number of deaths is insufficient for any type of statistical evaluation and illustrates what was stated earlier, that no definite conclusions can be drawn from the data available in any one company.

Among the observed deaths, cancer of all types accounted for four, or 44%. Two deaths were due to malignant melanoma, one to cancer of the rectum, and one to hemorrhage of a pituitary tumor. One of the melanoma cases was the only death among the nine that was confirmed by autopsy.

Application of the calculation to the Union Carbide findings results in an SMR of 23.6 in the 5,545 person-years accumulated by the 375 workers in the known cohort. Even though SMR's for working populations are expected to be less than for the general population, a deficit of the magnitude found here must be considered somewhat suspect. The inability to confirm precisely the status of the 35 persons whose employment records were never found would be a matter that would be of great concern to any statistician who might review the results of this study.

No significantly high risks in mortality were observed, as might be expected from the low SMR. No attempt was made at this time to make comparisons with SMR's for other industry groups, as for example, steelworkers, because the calculated SMR in this study is so very low.

MORBIDITY

As previously mentioned, since no illnesses leading to death have been associated with exposures to this group of chemicals, confining the study to mortality did not seem to offer the degree of information yield which might be gained by also looking at morbidity experience. Sickness and accident records, had they been available, would have provided easily accessible data on all workers absent for seven days or more on account of illness, including the diagnosis and duration. In their absence, it became necessary to inspect the individual dispensary records. Nurses records, physical examination results, and laboratory tests for all workers in the cohort were reviewed by the same board certified occupational physician in the interest of uniformity, except that those records for which we did not have a signed authorization were reviewed by Union Carbide medical personnel. A dictionary of the 8th edition, International Classification of Diseases, Adapted, was compiled by a second physician who also assigned these codes to the recorded complaints and diagnoses contained in the dispensary records. Of 375 persons in the cohort, medical records were obtained on 363.

Relative risks for the main classification of disease are shown by area or "zone," in the table on page 15.

Union Carbide trial exhibit UC-4189: Industrial Health Foundation Report to Union Carbide on an Epidemiology Stu... Published by AsbestosClaims.Law
ACL Doc 18783 · Page 16 of 104 asbestosclaims.law/library/18783/16

These relative risk tables are constructed as follows:

1. The plant was divided into work zones (described in "Silicone Industry Study Job Titles Listing by Work Area and Exposure Zone" -- see Appendix).

2. The following disease groupings were considered:

A. 8th ICDA codes -- 140-209 (all cancers)

B. 8th ICDA codes -- 390-448 (major cardiovascular diseases)

C. 8th ICDA codes -- 470-513 (nonmalignant respiratory diseases)

D. 8th ICDA code -- 250 (diabetes)

E. 8th ICDA codes -- 570-573 (all liver diseases)

F. 8th ICDA code -- 571 (cirrhosis)

G. Positive laboratory tests for increased thymol turbidity, increased liver enzymes, abnormal liver scan.

H. 8th ICDA codes -- 680-709 (diseases of skin and subcutaneous tissue)

I. 8th ICDA codes -- 582-584, 592-593 (kidney and urinary disease)

3. The entries in the tables are the estimated relative risks for an employee in a particular zone as opposed to an employee not in that zone. For example, an employee who has worked in zone 8 is 2.16 times more likely to have skin conditions reported on his medical record than an employee who never worked there.

4. A worker is included in a zone if he worked there for one month or more. Hence, the same employee may be included in more than one zone.

Union Carbide trial exhibit UC-4189: Industrial Health Foundation Report to Union Carbide on an Epidemiology Stu... Published by AsbestosClaims.Law
ACL Doc 18783 · Page 17 of 104 asbestosclaims.law/library/18783/17

5. A person is considered to have had a disease if it appears on his medical record at least once.

6. The total number of employees who have had a disease or who have worked in a particular zone appear at the bottom of the page, at the right.

7. Each relative risk was subjected to the chi-square test, although these are not included in the table. When the chi-square was significant at the .05 level, that fact is noted by one asterisk, and at the .01 level, by two asterisks above the relative risks.

8. When a disease classification or work zone contained less than 10 employees, the risk shown is enclosed in parentheses.

9. Great care should be taken in interpreting these findings since a host of selection factors or biases may be present in terms of the kind and amount of medical data available for workers in specific work zones.

Published by AsbestosClaims.Law
asbestosclaims.law/library/18783/19

Only three of the relative risks proved to be of significance in the study of Union Carbide medical records. An employee who has, at sometime, worked in zone 3 is 35.5 times as likely to have had diabetes than an employee who never worked in zone 3. This value is significant at the .05 level but not at the .01 level. Furthermore, fewer than 10 employees in the study were reported to have diabetes and the actual significance of this number is slight. Zone 8 showed a relative risk of 2.16 for dermatological conditions and zone 14 showed about the same. Because of a lower number of expected cases in zone 14, the 2.14 relative risk is significant at the .01 level, whereas, the 2.16 relative risk in zone 8 is significant only at the .05 level. The largest number of diagnoses were related to skin conditions, and for this reason the experience in these two zones is of considerable importance.

CONCLUSIONS AND RECOMMENDATIONS

As mentioned several times, because of the small number of people involved, no definite conclusions can be drawn except that, if the 375 workers constituted the total cohort, this plant has experienced remarkably good mortality. If all employment records had been available the conclusions drawn could have been much more firm. All that can be said under the existing circumstances is that a careful follow-up

asbestosclaims.law/library/18783/20

on 375 workers who had at least five years of exposure resulted in the finding of only nine deaths, giving an SMR of 23.6 in 5,545 accumulated person-years. Although four of the nine deaths were due to malignancies, there was no work area common to these four employees. The same weakness applies to the overall study, as pointed out in the composite report, because some companies were unable to furnish complete seniority lists. For this reason, it is recommended that the entire study be validated to the extent possible by means of a thorough cross-checking of Social Security numbers for accounts on which the companies made payments against the Social Security numbers of the workers in the study. In addition, the study could possibly be strengthened by including persons with one or more years of exposure, rather than five years, although it is unlikely that an exposure of less than five years would produce a result that would materially change the findings.

Although with Mr. Voisinet's help every effort was made to include persons now in the exempt category who had at one time held exposed jobs, it is recommended that a closer examination be made of such individuals.

Finally, it is recommended that the study of this total cohort be continued into the future on the format established by this study so that, as deaths occur, a more complete record of the mortality causes can be accumulated.
