Annual screening for employees who have a regular potential exposure to asbestos has been completed by the Medical Division. This consisted of chest x-ray, spirometry, respiratory disease questionnaire, chest examination, and, in most cases, a sputum examination. Chest x-rays were referred to a radiological specialist for interpretation. This report is attached. Sputum examinations which were done showed no evidence of malignancy or asbestosis. Any abnormalities noted in the spirometry pulmonary function studies were brought to your attention at the time of the chest examination. Smokers were and are urged to stop the use of tobacco because of the increased hazard of smoking and asbestos exposure.

If you have any questions concerning the results of any of these procedures, do not hesitate to contact the Medical Division.

Sincerely,

David H. Glenn, M.D.
Medical Director,
Gulf Coast Area
